1.1 Communicating Sequential Processes

Rewrite this section

add examples of a process and channels

The problem with multiprocessor workloads is the sharing of memory. This creates a whole slew of problems. There are many different processes going on at once all having access to the same memory. Unless you got superpowers it is very hard to determine where in the program something goes wrong. It all boils down to the non-determinism.

For example if you are going to print multiple strings using multiple threads you don't know which string i going to be printed first it's gonna depend on the operating system not on anything in your code. That can create race conditions (meaning the behaviour in your code is dependent on the timing of different threads) which can cause unpredictable behaviour and therefore bugs which is undesirable.

This has been tried to been solved with mutexes or locks but this also have its downside inform of deadlocks where multiple processes are waiting for each other and because these processes are non-deterministic it is very hard to reproduce errors in your code which in turn makes it hard to debug and therefore hard to make reliable software.

This is where Communicating Sequential Processes (CSP) comes in. CSP was an algebra first proposed by Hoare [1]. CSP is build on two very basic primitives one is the process (which should not be confused with operating system processes) which could be an ordered sequence of operations. These processes do not share any memory so one process cannot access a specific value in another process (which solves a lot the problems we had with shared memory).

The other primitive is channels which is the way the processes communicate which each other. You can pass whatever you want through these channels and once you pass a value you loose access to it.

There is a lot of ways the processes and channels can be arranged the most simple one can be found in figure 1.1 which illustrates process 1 which passes a value onto a channel which process 2 takes as input. Some different configuations can be found in figures 1.2-1.4

Chapter 2

Logic Design

This chapter aims to introduce the reader to the basics of logic design, which will be imperative to the understanding the subsequent chapters. The general structure of this chapter will be based on Appendix A in [2].

Chapter sections are subject to change in name and order

We will begin in section 2.1 by introducing the fundamental algebra and the physical building blocks, used to implement the algebra, such as the OR gate.

Hereafter we will be using these building blocks to design and create the core components used in the RISC-V architecture such as the decoder and multiplexer in section 2.2.

2.1 Boolean algebra

The fundamental tool used in logic design is a branch of mathematical logic called Boolean algebra. Compared to elementary algebra, where we deal with variables which represents some real or complex number, in Boolean algebra the variables are viewed as statements or propositions which is either *true* or *false*.

In addition to the variables in elementary algebra we also had a means of manipulating them. These manipulations are called operations which operates on the variables (operands) where the basic operators of algebra consists of

- The addition ($+$) operator which finds the total amount between two given operands.
- The subtraction ($-$) operator which finds the difference between two given operands.
- The multiplication ($\cdot$) operator which repeats the addition operation a given number of times. For example $3 \cdot 4 = 12$ would then be 3 times the addition operation with 4 as the variable $4 + 4 + 4 = 12$.
- The division ($\div$) operator which can be viewed as the inverse of the multiplication operation. For example as before we had $3 \cdot 4 = 12$ and to inverse it we would divide the right hand side like so $3 = 12 \div 4$.

In Boolean algebra we have a distinction between operators which work on one operand and the ones that work on to two operands. These are called unary and binary operators respectively. We would go through a description of these in the following section.

2.1.1 Unary operators

make ven diagrams to show the operator function

With a single binary operand p we have 2 possible input $true$ and $false$. All output combinations are summarized in table 2.1. Each numbered column here represents an undefined operator. We will go ahead and define these in the following.

p	1	2	3	4
$true$	$true$	$true$	$false$	$false$
$false$	$true$	$false$	$true$	$false$

Table 2.1: Logic table of possible unary operators. Each numbered column represents an undefined operator.

Logical complement

For our first basic Boolean operator we have the logical complement operator, which is represented by NOT, !, $\neg$ or $\bar{x}$ in various literature and commonly referred to as the negation operator.

The negation operator inverts an operand such that $\neg true = false$ and $\neg false = true$. Using a table we can neatly represent the complete function of the negation operator. These tables are called *logic tables*.

A logic table has been created for the negation operator as can be seen in table 2.2. The first column represents our proposition and all its possible arguments $true$ and $false$. The second column is then the negated proposition.

p	$\neg p$
$true$	$false$
$false$	$true$

Table 2.2: Logic table of the negation operator where the proposition p, which is either true or false, can be found in the first column. In the second column we find $\neg p$, which is read as NOT p, and its return values.

Logical identity

Hereafter we have the logical identity operator which we will represent as the function $I(x)$. The logical identity operator takes an argument and returns it as is.

A logic table for the identity operator has been created and can be found in table 2.3. In the first column we find our preposition p and its arguments. In the second column we find the return values of the identity operator with the prepositions as the argument $I(p)$.

p	$I(p)$
$true$	$true$
$false$	$false$

Table 2.3: Logic table of the identity operator where the proposition p, which is either true or false, can be found in the first column. In the second column we find $I(p)$, which is the identity operator with p as its argument, and its return values.

Logical true

Next we have logical true which we will represent as the function $T(x)$. Logical true takes an argument and always returns true.

A logic table for the true operator has been created and can be found in table 2.4. In the first column we find our preposition p and its arguments. In the second column we find the return values of the true operator with the prepositions as the argument $T(p)$.

p	$T(p)$
$true$	$true$
$false$	$true$

Table 2.4: Logic table of the true operator where the proposition p, which is either true or false, can be found in the first column. In the second column we find $T(p)$, which is the true operator with p as its argument, and its return values.

Logical false

Lastly we have logical false which we will represent as the function $F(x)$. Logical false takes an argument and always return false.

A logic table for the false operator has been created and can be found in table 2.5. In the first column we find our preposition p and its arguments. In the second column we find the return values of the false operator with the prepositions as the argument $F(p)$.

p	$F(p)$
$true$	$false$
$false$	$false$

Table 2.5: Logic table of the false operator where the proposition p, which is either true or false, can be found in the first column. In the second column we find $F(p)$, which is the false operator with p as its argument, and its return values.

Summary

We can now go ahead and fill the numbered columns table 2.1 with the corresponding operators which we have defined throughout this section. The filled table can be found in table 2.6.

rewrite this section.

p	$T(p)$	$I(p)$	$\neg p$	$F(p)$
$true$	$true$	$true$	$false$	$false$
$false$	$true$	$false$	$true$	$false$

Table 2.6: Logic table of possible unary operators. Each numbered column represents an undefined operator.

2.1.2 Binary operators and disjunctive normal form

With two binary operands, p and q, there exist four possible combinations between their respectable values namely $(true, true)$, $(true, false)$, $(false, true)$, $(false, false)$.

Compared to the previous section we now have 4 possible input values to our yet undefined operators $X(p, q)$. There exist 16 unique sets of outputs and therefore 16 possible operators. An example of a set of outputs could be

$$X(p, q) = \{true, false, false, false\} \tag{2.1}$$

where $(p, q) = \{(true, true), (true, false), (false, true), (false, false)\}$ is the set of possible inputs.

All output sets are summarized in table 2.7 where each numbered column represents an undefined operator.

We will in this section start by defining the basic operators from which we will derive the rest. For brevity we will only go through the 6 most commonly used operators, the rest can be referred to in appendix A.

The choice of basic operators is arbitrary but I have chosen the operators for which it is the easiest to derive all other operators, since there exists a method to convert any truth table into a Boolean expression using these which we will get into later.

p	q	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
t	t	t	t	t	t	f	t	f	f	t	t	f	t	f	f	f	f
t	f	t	t	t	f	t	t	t	f	f	f	t	f	t	f	f	f
f	t	t	t	f	t	t	f	t	t	f	t	f	f	f	t	f	f
f	f	t	f	t	t	t	f	f	t	t	f	t	f	f	f	t	f

Table 2.7: Logic table of possible binary operators where $t = true$ and $f = false$. Each numbered column represents an undefined operator.

Logical conjunction

The logical conjunction operator is represented by $\wedge$ in mathematics; AND, &, && in computer science and a $\cdot$ in electronic engineering and commonly referred to as the AND operator or the logical product. The AND operator only results in a true value if both of the operands are true.

remember to tell why this is later

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 12 and is summarized in table 2.8.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the AND operation between p and q.

p	q	$p \wedge q$
$true$	$true$	$true$
$true$	$false$	$false$
$false$	$true$	$false$
$false$	$false$	$false$

Table 2.8: Logic table of the AND operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the AND operation between p and q.

Logical disjunction

The logical disjunction operator is represented by $\vee$ in mathematics; OR, |, || in computer science and a + in electronic engineering and commonly referred to as the OR operator or the logical sum. The OR operator results in a true value if one or more of the operands are true.

remember to tell why this is later

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 2 and is summarized in table 2.9.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the OR operation between p and q.

We choose AND, OR and NOT to form our basic or primitive operators from which we will derive all remaining operators.

Exclusive disjunction and disjunctive normal form

The exclusive disjunction is represented by $\veebar$ in mathematics or XOR, ^ in computer science and commonly referred to as the XOR or exclusive OR operator. The XOR operator results in a true value only if the operands differ.

p	q	$p \lor q$
$true$	$true$	$true$
$true$	$false$	$true$
$false$	$true$	$true$
$false$	$false$	$false$

Table 2.9: Logic table of the OR operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the OR operation between p and q.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 7 and is summarized in table 2.10.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the XOR operation between p and q.

p	q	$p \veebar q$
$true$	$true$	$false$
$true$	$false$	$true$
$false$	$true$	$true$
$false$	$false$	$false$

Table 2.10: Logic table of the XOR operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the XOR operation between p and q.

We can define this operator in disjunctive normal form using our basic operators AND, OR and NOT.

To do this we first identify all true output in 2.10 namely row 3 and 4. We then take a look at the corresponding input values

$$(p, q) = (true, false) \quad \text{and} \quad (p, q) = (false, true) \tag{2.2}$$

and applying the NOT operator on all the false values. We now have the two tuples

$$(p, \neg q) = (true, \neg false) \quad \text{and} \quad (\neg p, q) = (\neg false, true). \tag{2.3}$$

Hereafter we apply the AND operator between the values in each tuple of input such that

$$p \land \neg q = true \land \neg false \quad \text{and} \quad \neg p \land q = false \land \neg true. \tag{2.4}$$

Lastly we apply the OR operators between each tuple and we have the final expression for

XOR in terms of the basic operators

$$p \veebar q = (p \wedge \neg q) \vee (\neg p \wedge q). \tag{2.5}$$

The procedure is summarized as follows

1. Find all output values which is true.
2. Negate all false input for corresponding true output value.
3. Apply AND operator between each value in each input tuple.
4. Lastly apply OR operator between each input tuple.

Using this procedure any logic table can be expressed as a Boolean expression and will be used extensively throughout this thesis.

Joint denial

Joint denial is represented by $\downarrow$ in mathematics or NOR in computer science and commonly referred to as the NOR operator. The NOR operator results in a true value only if both operands are false.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 15 and is summarized in table 2.11.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the NOR operation between p and q.

p	q	$p \downarrow q$
$true$	$true$	$false$
$true$	$false$	$false$
$false$	$true$	$false$
$false$	$false$	$true$

Table 2.11: Logic table of the NOR operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the NOR operation between p and q.

In disjunctive normal form the NOR operator can be expressed in the following form

$$p \downarrow q = (\neg p \wedge \neg q) \tag{2.6}$$

using the procedure previously mentioned.

Alternative denial

Alternative denial is represented by $\uparrow$ in mathematics or NAND in computer science and commonly referred to as the NAND operator. The NAND operator results in a true value only if one or more of the operands are false.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 5 and is summarized in table 2.12.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the NAND operation between p and q.

p	q	$p \uparrow q$
$true$	$true$	$false$
$true$	$false$	$true$
$false$	$true$	$true$
$false$	$false$	$true$

Table 2.12: Logic table of the NAND operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the NAND operation between p and q.

In disjunctive normal form the NAND operator can be expressed in the following form

$$p \uparrow q = (p \wedge \neg q) \vee (\neg p \wedge q) \vee (\neg p \wedge \neg q) \tag{2.7}$$

using the procedure previously mentioned.

Logical biconditional

The logical biconditional is represented by $\leftrightarrow$ in mathematics or XNOR in computer science and commonly referred to as the exclusive NOR operator. The XNOR operator results in a true value only if both operands are either true or false.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 9 and is summarized in table 2.13.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the XNOR operation between p and q.

In disjunctive normal form the XNOR operator can be expressed in the following form

$$p \leftrightarrow q = (p \wedge q) \vee (\neg p \wedge \neg q) \tag{2.8}$$

using the procedure previously mentioned.

p	q	$p \leftrightarrow q$
$true$	$true$	$true$
$true$	$false$	$false$
$false$	$true$	$false$
$false$	$false$	$true$

Table 2.13: Logic table of the XNOR operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the XNOR operation between p and q.

Summary

We can now go ahead and fill the numbered columns table 2.7 with the corresponding operators which we have defined throughout this section. The filled table can be found in table 2.14.

rewrite this section.

p	q	$\top$	$\vee$	$\leftarrow$	$\rightarrow$	$\uparrow$	$P(p,q)$	$\veebar$	$\neg P(p,q)$	$\leftrightarrow$	$Q(p,q)$	$\neg Q(p,q)$	$\wedge$	$\not\rightarrow$	$\not\leftarrow$	$\downarrow$	$\bot$

Binary Operators

Tautology

The tautology operator is represented by $\top$ in mathematics which always returns a true value.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 1 and is summarized in table A.1.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the tautology operation between p and q.

p	q	$p \top q$
$true$	$true$	$true$
$true$	$false$	$true$
$false$	$true$	$true$
$false$	$false$	$true$

Table A.1: Logic table of the tautology operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the tautology operation between p and q.

In disjunctive normal form the tautology operator can be expressed in the following form

$$p \top q = (p \wedge q) \vee (p \wedge \neg q) \vee (\neg p \wedge q) \vee (\neg p \wedge \neg q) \tag{A.1}$$

using the procedure mentioned in chapter 2.1.

Contradiction

The contradiction operator is represented by $\perp$ in mathematics which always returns a false value.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 16 and is summarized in table A.2.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the contradiction operator between p and q.

p	q	$p \bot q$
$true$	$true$	$false$
$true$	$false$	$false$
$false$	$true$	$false$
$false$	$false$	$false$

Table A.2: Logic table of the contradiction operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the contradiction operation between p and q.

In disjunctive normal form the contradiction operator can be expressed in the following form

$$p \bot q = p \wedge \neg p \tag{A.2}$$

Proposition P

We will define the operator Proposition P which results in a true value only if the first operand p is true.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 6 and is summarized in table A.3.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the proposition P between p and q.

p	q	$P(p,q)$
$true$	$true$	$true$
$true$	$false$	$true$
$false$	$true$	$false$
$false$	$false$	$false$

Table A.3: Logic table of the proposition P operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the proposition P operation between p and q.

In disjunctive normal form the proposition P can be expressed in the following form

$$P(p,q) = (p \wedge q) \vee (p \wedge \neg q) \tag{A.3}$$

using the procedure mentioned in chapter 2.1.

Proposition Q

We will define the operator Proposition Q which results in a true value only if the second operand q is true.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 10 and is summarized in table A.4.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the proposition Q between p and q.

p	q	$Q(p,q)$
$true$	$true$	$true$
$true$	$false$	$false$
$false$	$true$	$true$
$false$	$false$	$false$

Table A.4: Logic table of the proposition P operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the proposition P operation between p and q.

In disjunctive normal form the proposition Q can be expressed in the following form

$$P(p,q) = (p \wedge q) \vee (\neg p \wedge q) \tag{A.4}$$

using the procedure mentioned in chapter 2.1.

Negated P

We will define the operator negated P which results in a true value only if the first operand p is false.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 8 and is summarized in table A.5.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the negated P between p and q.

In disjunctive normal form the negated P can be expressed in the following form

$$\neg P(p,q) = (\neg p \wedge q) \vee (\neg p \wedge \neg q) \tag{A.5}$$

using the procedure mentioned in chapter 2.1.

p	q	$\neg P(p,q)$
$true$	$true$	$false$
$true$	$false$	$false$
$false$	$true$	$true$
$false$	$false$	$true$

Table A.5: Logic table of the negated P operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the negated P operation between p and q.

Negated Q

We will define the operator negated Q which results in a true value only if the second operand q is false.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 11 and is summarized in table A.6.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the negated Q between p and q.

p	q	$\neg Q(p,q)$
$true$	$true$	$false$
$true$	$false$	$true$
$false$	$true$	$false$
$false$	$false$	$true$

Table A.6: Logic table of the negated Q operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the negated operation between p and q.

In disjunctive normal form the negated Q can be expressed in the following form

$$\neg Q(p,q) = (p \wedge \neg q) \vee (\neg p \wedge \neg q) \tag{A.6}$$

using the procedure mentioned in chapter 2.1.

Material implication

Material implication is represented by $\rightarrow$ in mathematics. The material implication operator results in a false value only if the first operand p is true and second operand q is false.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 4 and is summarized in table A.7.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the material implication operation between p and q.

p	q	$p \rightarrow q$
$true$	$true$	$true$
$true$	$false$	$false$
$false$	$true$	$true$
$false$	$false$	$true$

Table A.7: Logic table of the material implication operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the material implication operation between p and q.

In disjunctive normal form the material implication operator can be expressed in the following form

$$p \rightarrow q = (p \wedge q) \vee (\neg p \wedge q) \vee (\neg p \wedge \neg q) \tag{A.7}$$

using the procedure mentioned in chapter 2.1.

Converse implication

Converse implication is represented by $\leftarrow$ in mathematics. The converse implication operator results in a false value only if the first operand p is true and the second q is true.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 3 and is summarized in table A.8.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the converse implication operation between p and q.

p	q	$p \leftarrow q$
$true$	$true$	$true$
$true$	$false$	$true$
$false$	$true$	$false$
$false$	$false$	$true$

Table A.8: Logic table of the converse implication operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the converse implication operation between p and q.

In disjunctive normal form the converse implication operator can be expressed in the following form

$$p \leftarrow q = (p \wedge q) \vee (p \wedge \neg q) \vee (\neg p \wedge \neg q) \tag{A.8}$$

using the procedure mentioned in chapter 2.1.

Material nonimplication

Material nonimplication is represented by $\nrightarrow$ in mathematics. The material nonimplication operator results in a true value only if the first operand p is true and the second operand q is false.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 13 and is summarized in table A.9.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the material nonimplication operation between p and q.

p	q	$p \nrightarrow q$
$true$	$true$	$false$
$true$	$false$	$true$
$false$	$true$	$false$
$false$	$false$	$false$

Table A.9: Logic table of the material nonimplication operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the material nonimplication operation between p and q.

In disjunctive normal form the material nonimplication operator can be expressed in the following form

$$p \rightarrow q = p \wedge \neg q \tag{A.9}$$

using the procedure mentioned in chapter 2.1.

Converse nonimplication

Converse nonimplication is represented by $\nleftarrow$ in mathematics. The converse nonimplication operator results in a true value only if the first operand p is false and the second operand q is true.

Using table 2.7 we see that the set of outputs which corresponds to this definition is column 14 and is summarized in table A.10.

Here we have the propositions p and q in the first two columns and all possible permutations between them in the following rows. The last column then shows the resulting value after doing the converse nonimplication operation between p and q.

In disjunctive normal form the converse nonimplication operator can be expressed in the following form

$$p \leftarrow q = \neg p \wedge q \tag{A.10}$$

using the procedure mentioned in chapter 2.1.

p	q	$p \nleftarrow q$
$true$	$true$	$false$
$true$	$false$	$false$
$false$	$true$	$true$
$false$	$false$	$false$

Table A.10: Logic table of the converse nonimplication operator where p is the first proposition and q is the second. All possible permutations are then specified in each row for each proposition. The third column then shows the resulting value of the converse nonimplication operation between p and q.

imm[20|10:1|11|19:12]				rd	opcode	J-type

* This is a special case of the RV64I I-type format used by slli, srli and srai instructions where the lower 6 bits in the immediate are used to determine the shift amount (shamt). If slliw, srliw and sraiw are used it should generate an error if imm[6] $\neq 0$
